Abstract—This paper presents kinematic control problem of skid-steering mobile robot using practical smooth and time-varying stabilizer. The stability result is proved using Lyapunov analysis and takes into account both input signal saturation and uncertainty of kinematics. In order to ensure stable motion of the robot the condition of permissible velocities is formulated according to dynamic model and wheel-surface interaction. Theoretical considerations are illustrated by simulation results.

I. INTRODUCTION

Considering ground wheeled vehicles one can distinguish two main categories, i.e. vehicles for which non-slip and pure-rolling conditions may be assumed [3] and vehicles for which skid phenomena is used for proper operation. Although skidding effect between wheels and surface may be observed for all vehicles, only for the second group known as skid-steering vehicles it is necessary to change their heading.

Skid-steering structure is commonly used in robotics that is due to its simplicity and mechanical robustness. In particular skid-steering mobile robots (SSMRs) are quite similar to robots equipped with two-wheeled differential driving system (i.e. unicycle-like robots). However, there is an important difference between them, namely for SSMR ground-wheels interaction and skidding effect play an important role within high range of velocities and accelerations (in contrast for other vehicles skidding is usually noticeable only for higher linear and angular velocities). Since ground reaction forces are very difficult to calculate and measure the model of SSMR dynamics is not accurate. Moreover, in spite of that fact that skidding is necessary to change robot’s orientation, extensive skidding causes the motion to be unstable – hence it is necessary to limit velocity of the vehicle.

Control problem for SSMR is quite challenging mainly because of two facts. Firstly, SSMR is an underactuated system and secondly, its mathematical model is highly uncertain. In the robotics literature not much has been written about controlling of SSMR using formal mathematical approach and stability analysis. In some papers (see [2] and [8]) for control purposes authors assumed an ideal nonholonomic constraint which cannot be enforced in practice. Additionally, linear techniques presented in [2] do not allow to solve stabilization problem because of Brockett's obstruction [1] and to control orientation directly (only position tracking is considered).

In this paper we propose to treat SSMR as system subjected to non ideal nonintegrable constraint. Next, we formulate kinematic control law based on tunable oscillator [4] and transverse functions [5] which is robust to uncertain bounded kinematic parameter. Taking into account the part of dynamics we give a condition of stable motion with respect to position of instantaneous center of rotation.

Here we consider control problem assuming that linear and angular velocity can be treated as control input and neglect the task of enforcing this velocities by actuators. Such approach is used for dividing control tasks onto two levels, i.e. kinematic and dynamic and can be relatively easy used in real applications.

The paper is organized as follows. In Section II kinematic and dynamic model of SSMR is presented and condition of stable motion is formulated. In the next section the control law using tunable oscillator is developed with respect to limited kinematic uncertainty and formal proof of stability is given. In order to limit robot velocity scaling algorithm is proposed. In Section IV simulation results are presented. Concluding remarks are given in Section V.

II. MODEL OF SSMR ROBOT

A. Kinematics

Consider a Four Wheel Drive (4-WD) SSMR placed on the plane (Fig. 1) with inertial frame $X_0Y_0Z_0$ and define a local frame $x_1y_1z_1$ attached to its center of mass (COM). Let $q = [X\ Y\ \theta]^T \in \mathbb{R}^3 \times \mathbb{S}$ denotes generalized coordinates describing robot’s position, $X$ and $Y$, in the inertial frame and orientation, $\theta$, of the local frame with respect to the inertial one.

Next, assume that the robot moves with velocity vector $\dot{q}$. In the local frame one can describe robot motion using vector $\eta = [v_x\ v_y\ \omega]^T \in \mathbb{R}^3$, where $v_x$, $v_y$ and $\omega$ denotes longitudinal, lateral and angular velocity of the robot, respectively. From Fig. 1 one can easily find the following tangent map

$$\eta = J(q) \dot{q}, \quad \text{(1)}$$

where $J = \begin{bmatrix} R^T(\theta) & 0 \\ 0 & 1 \end{bmatrix}$ is a Jacobian matrix with $R(\theta) \in \mathbb{S}^0(2)$. 

...
Taking into account position of instantaneous center of rotation (ICR) one can find the following important relationship
\[
\begin{align*}
\frac{v_x}{y_{ICR}} = \frac{-v_y}{x_{ICR}} = \omega, \\
\end{align*}
\]
where \(x_{ICR}\) and \(y_{ICR}\) are coordinates of ICR expressed in the local frame.

**B. Dynamics**

The dynamics of SSMR can be modeled using the following equation (for details see [8])
\[
M(q)\dot{q} + F(q) = B(q)\tau,
\]
where \(M \in \mathbb{R}^{3 \times 3}\) denotes the constant, positive definite inertia matrix, \(F(q) \in \mathbb{R}^3\) is vector of resultant reactive forces and torque, \(B(q) \in \mathbb{R}^{3 \times 2}\) denotes input matrix, \(\tau = [\tau_L \tau_R]^T \in \mathbb{R}^2\) is an input vector determining torques produced by pairs of wheels on the left and right side of the vehicle, respectively. For simplicity we assume that mass distribution of the vehicle is homogeneous – hence, inertia matrix takes the following form: \(M = \text{diag} \{m, m, I\}\), while \(m, I\) represents the mass and inertia, respectively.

![Fig. 1. Kinematics of SSMR](image)

It should be noted that determination of \(F(q)\) is quite difficult since it results from complicated wheel-ground interaction phenomena. In this paper in order to describe reactive lateral forces \(F_{ri} (i = 1, 2, 3, 4)\) (see Fig. 2) we use the following Coulomb friction model:
\[
F_{ri}(v_{yi}) = \mu_i N_i \text{sgn}(v_{yi}),
\]
where \(\mu_i\) and \(v_{yi}\) determine friction coefficient and lateral velocity of the point \(P_i\) where \(i\)-th wheel touches surface (see Fig. 1) and \(N_i\) is wheel ground contact force which result from gravity.

For control purpose it is convenient to rewrite dynamic equation (3) using kinematic relationship (1) in the following form
\[
M \ddot{\eta} + C \dot{\eta} + F = B\tau,
\]
where
\[
M = M, \quad F = [0 \quad F_r \quad M_r]^T,
\]
\[
C = \begin{bmatrix}
0 & -m & 0 \\
-1 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix} \omega, \quad B = \frac{1}{r} \begin{bmatrix}
1 & 1 \\
0 & 0 \\
-c & c
\end{bmatrix},
\]
with
\[
F_r = \sum_{i=1}^{4} F_{ri}(v_{yi}), \quad M_r(q) = -a \sum_{i=1,4} F_{ri}(v_{yi}) + b \sum_{i=2,3} F_{ri}(v_{yi})
\]
and \(r = r_i\) (it is supposed that radius of each wheel is the same).

**C. Stable motion analysis**

Skidding effect for SSMR is a necessary condition for changing its orientation. However, extensive skidding results in unstable motion. In order to describe skidding effect we consider SSMR dynamics.

Firstly let us rewrite dynamic equation (5) in the more detailed form
\[
\begin{bmatrix}
m \dot{v}_x \\
m \dot{v}_y \\
I \dot{\omega}
\end{bmatrix} + \begin{bmatrix}
-\frac{m v_y \omega}{m v_y} \\
\frac{m v_x \omega}{m v_y} \\
0
\end{bmatrix} + \begin{bmatrix}
0 \\
F_r \\
M_r(q)
\end{bmatrix} = \frac{1}{r} \begin{bmatrix}
\tau_L + \tau_R \\
0 \\
\frac{\omega}{c} (\tau_L - \tau_R)
\end{bmatrix}.
\]

From (7) one can see that variables \(v_x\) and \(\omega\) can be controlled by torque signals relatively easy but \(v_y\) is not directly related to input. Notice that lateral velocity is related to ground-wheel interaction and product of longitudinal and angular velocities of the robot.

Now we will give necessary condition to limit \(v_y\) in order to decrease skidding magnitude. Calculating reactive force \(F_r\) and velocities \(v_{yi}\) using position of ICR one can obtain that
\[
F_r = -[\mu_i N_i + \mu_i N_i] \text{sgn}(x_{ICR} + a) + \mu_i N_i \text{sgn}(-x_{ICR} + b) \text{sgn}(\omega).
\]

Notice that \(F_r\) is strictly related to \(x\)-coordinate of ICR position. Next we introduce the following sets
\[
X_{in} \triangleq \{x_{ICR} \in \mathbb{R} : -a < x_{ICR} < b\}, \\
X_{out} \triangleq \{x_{ICR} \in \mathbb{R} : x_{ICR} < -a\}, \\
X_{out2} \triangleq \{x_{ICR} \in \mathbb{R} : x_{ICR} > b\}.
\]
and calculate the resultant reactive force as

\[
F_r = sgn(\omega) \cdot F_r
\]

(10)

where

\[
F_A \triangleq \sum_{i=1}^4 \mu_i N_i, \quad F_B \triangleq \sum_{i=2,3} \mu_i N_i, \\
F_C \triangleq -\sum_{i=1,4} \mu_i N_i + \sum_{i=2,3} \mu_i N_i, \\
F_D \triangleq -\sum_{i=1,4} \mu_i N_i, \quad F_E \triangleq -\sum_{i=1}^4 \mu_i N_i.
\]

Next recalling (7) one may write

\[
v_y = \omega x_{ICR} - \omega x_{ICR}.
\]

(13)

which leads to the following linear differential equation with time-varying coefficients

\[
\dot{v}_y = -\omega x_{ICR} - \omega x_{ICR} = v_y \omega + \frac{F_r}{m}.
\]

(14)

In order to consider evolution of \( x_{ICR} \) during the robot’s movement we simplify analysis assuming that angular velocity is constant (\( \omega = 0 \)). Then one can easily find the solution of (14) as follows

\[
x_{ICR}(t) = x_{ICR}(t_0) + \int_{t_0}^{t} \left( v_y(\sigma) + \frac{F_r(\sigma)}{\omega m} \right) d\sigma.
\]

(15)

Next using the result (15) and taking into account that \( F_r \) magnitude achieves maximum if \( x_{ICR} \) is in the set \( X_{out} \) or \( X_{out} \)(notice from (11) that \( F_A > F_C \) and \( F_E < F_C \)) one may formulate the following proposition.

**Proposition 1:** Assuming that linear and angular velocities of the vehicle satisfy

\[
|\omega v_x| \leq \frac{1}{m} \sum_{i=1}^4 \mu_i N_i
\]

(16)

the motion of the vehicle is stable in the sense that \( x \)-coordinate of ICR is bounded as

\[
-a \leq x_{ICR} \leq b.
\]

(17)

Then define a maximum magnitude of product of longitudinal and angular velocities which satisfies (16)

\[
\Gamma \triangleq \max |\omega v_x|.
\]

(18)

### III. Control Development

#### A. Kinematic model reformulation

Recalling kinematic equation (1) one can write that

\[
\dot{q} = \begin{bmatrix} \cos \theta & 0 & -v_y \\ \sin \theta & 0 & v_y \\ 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} v_x \\ \omega \\ 0 \end{bmatrix} + \begin{bmatrix} -\sin \theta \\ \cos \theta \\ 0 \end{bmatrix} v_y.
\]

(19)

Accordingly SSMR kinematics can be approximated by kinematics of nonholonomic unicycle-like vehicle perturbed by skidding effect introduced by \( v_y \) term. In this paper we assume that magnitude of \( v_y \) is bounded by scalar function \( \rho \), such that \( |v_y| < \frac{1}{2} \).

For control purpose the following tracking error is defined

\[
\bar{q} = \begin{bmatrix} \bar{q}_1 \\ \bar{q}_2 \\ \bar{q}_3 \end{bmatrix}^T = q - q_r,
\]

(20)

where \( q_r \) denotes reference position \( X_r, Y_r \) and orientation \( \theta_r \). Next, taking the time derivative of (20), using (1) and coordinates transformation introduced by Dixon et al. [4]

\[
x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} x^T \\ x_3 \end{bmatrix}^T = P(\theta, \bar{\theta}) \bar{q},
\]

(21)

with

\[
P(\theta, \bar{\theta}) = \begin{bmatrix} 0 & 0 & 1 \\ \cos \theta & \sin \theta & 0 \\ p_{11} & p_{12} & 0 \end{bmatrix}
\]

(22)

which \( p_{11} = -\bar{\theta} \cos \theta + 2 \sin \theta, p_{12} = -\bar{\theta} \sin \theta - 2 \cos \theta \) lead to the following auxiliary system

\[
\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \end{bmatrix} = \begin{bmatrix} u_1 \\ u_2 \\ f + d \end{bmatrix},
\]

(23)

where \( J = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \) is a skew-symmetric matrix, \( f(q, \dot{q}) \triangleq 2(-\dot{X}_x \cos \theta + \dot{Y}_r \sin \theta, \dot{\theta}, x_2) \) is the drift caused by reference time-varying signals and \( d \triangleq -2v_y \) is the disturbance introduced by skidding. Notice that in the case of regulation considered in this paper, when \( q_r = \text{const} \), one has \( f = 0 \).

#### B. Kinematic control law robust to the limited skidding

The kinematic control problem considered here can be defined as follows.

**Definition 1:** Find bounded controls \( v_x(t), \omega(t) \) for kinematics (1) such that for initial condition \( q(0) \in \mathbb{R}^3 \) the Euclidean norm of the error \( \bar{q}(t) \) tends to some constant \( \varepsilon > 0 \) as \( \tau \to \infty \):

\[
\lim_{t \to \infty} \|\bar{q}(t)\| \leq \varepsilon,
\]

(24)

where \( \varepsilon \) is an assumed error envelope, which can be made arbitrary small.

Firstly, for control design we consider a Lie group \( G = \mathbb{R}^3 \) with a smooth group operation [6]

\[
a \circ b = \begin{bmatrix} a_x + b_x \frac{b_y}{b_z} + \alpha^T J b \end{bmatrix},
\]

(25)
for any $a, b \in \mathcal{G}$. It is straightforward to verify that operation (25) is a left invariant operation for the system (23), i.e.
\[
\frac{d}{dt} \left( x_0 \circ x(t) \right) = g_1 \left( x_0 \circ x(t) \right) u_1 + g_2 \left( x_0 \circ x(t) \right) u_2,
\]  
(26)

where $x_0 \in \mathcal{G}$, $g_1(x) = [1 \quad 0 \quad x_2]$ and $g_2(x) = [0 \quad 1 \quad -x_1]$ are vector field generators.

Next taking into account (25), we introduce a new state vector
\[
z \triangleq x \circ x^{-1} \in \mathcal{G}
\]  
(27)

where $x_d = \left[ x_{d1} \quad x_{d2} \quad 0 \right]$ denotes an auxiliary time-varying signal and $x_d \circ x_d^{-1} = 0$. Similarly to [4] it is supposed that $x_d'$ is generated by linear tunable oscillator as follows
\[
x_d' \triangleq \Psi \xi,
\]  
(28)

where $\Psi = \begin{bmatrix} \psi_1 & 0 \\ 0 & \psi_2 \end{bmatrix}$ is positive definite gain matrix, $\xi \in \mathbb{R}^2$ is the solution of the following differential equation
\[
\dot{\xi} \triangleq u_{\omega} J \xi,
\]  
(29)

with $u_{\omega}$ denoting instantaneous frequency.

Considering (27) one can prove that (compare [6])
\[
z = \begin{bmatrix} x^* - x_d' \\ x_3 + x_d' T J x^* \end{bmatrix}.
\]  
(30)

Taking the time derivative of (30) and using (23) we have the following dynamical system
\[
\begin{bmatrix} \dot{z}_3 \\ \dot{z}_2 \end{bmatrix} = \begin{bmatrix} u - \dot{x}_d' \\ x_3 + \dot{x}_3 T J x^* + f + d \end{bmatrix}.
\]  
(31)

In order to stabilize it in the neighborhood of the origin the following proposition can be given.

Proposition 2: Assuming that $|d| < \rho \in \mathbb{R}^+$, $f \in \mathcal{L}_\infty$ the control law
\[
u = -k_1 z^* + \dot{x}_d
\]  
(32)

and
\[
u_{\omega} = \left( k_2 + \frac{\rho^2}{\rho |x_3| + \varepsilon_3} \right) z_3 + \xi^T \Psi^T J \Psi \xi + 2 k_1 x^T J x_{d}\]  
(33)

with gains $k_1, k_2 > 0$ and positive constant $\varepsilon_3$ ensures that tracking error signal $z$ is global ultimately uniformly bounded in the sense that
\[
\|z(t)\| \leq \sqrt{\|z(0)\| \exp(-2 \lambda t) + \frac{\varepsilon_3}{2 \lambda} [1 - \exp(-2 \lambda t)]},
\]  
(34)

where $\lambda = \min \{k_1, k_2\}$.

Proof: Consider Lyapunov function candidate with respect to $z_3$:
\[
V_1 = \frac{1}{2} z_3^2.
\]  
(35)

Next, taking the time derivative of (35) and substituting control (32) in (31) one has
\[
\dot{V}_1 = z_3 \left( -k_1 (x^* T + x_{d}' T) J z^* + x_d' T J x_d' + f + d \right).
\]  
(36)

Calculating the term $x_d' T J x_d'$ and using (33) yield
\[
\dot{V}_1 = -k_2 z_3^2 - \frac{\rho^2 z_3^2}{\rho |x_3| + \varepsilon_3} + d \cdot z_3.
\]  
(37)

Assuming that upper bound of $d$ is known one can write that
\[
\dot{V}_1 \leq -k_2 z_3^2 + \varepsilon_3
\]  
(38)

from which it can be concluded that
\[
z_3 \leq \sqrt{z_3(0) \exp(-2k_2 t) + \frac{\varepsilon_3}{2k_2} (1 - \exp(-2k_2 t))}.
\]  
(39)

Next, taking into account evolution of $x_1^*$ and using (32) in (31) one can easily write the following equation of closed-loop subsystem
\[
z^* = -k_1 z^*,
\]  
(40)

which leads to
\[
z^* (t) = z^* (0) \exp(-k_1 t).
\]  
(41)

In order to consider overall system (30) we define Lyapunov candidate function
\[
V = \frac{1}{2} z^T z.
\]  
(42)

Using the results given by (38) and (40) it is clear that
\[
\dot{V} \leq -k_1 z^* T z - k_2 z_3^2 + \varepsilon_3,
\]  
(43)

and it straightforward leads to the stability result given by (34).

In order to tune the controller we assume that matrix $\Psi$ is time varying with $\psi_1$ and $\psi_2$ satisfying
\[
\psi_i (t) = \psi_{i0} \exp(-\alpha_i t) + \varepsilon_i, \text{ for } i = 1, 2,
\]  
(44)

where $\psi_{i0} > 0$, $\alpha_i > 0$ and $\varepsilon_i > 0$ are scalar coefficients determining initial and limit value of functions $\psi_i$ and their convergence rate, respectively. Using such gain scheduling one can prove taking into account results (39) and (41) that in the steady-state elements of $x$ are bounded as
\[
\lim_{t \to \infty} |x_{11}| \leq \varepsilon_1, \lim_{t \to \infty} |x_{21}| \leq \varepsilon_2, \lim_{t \to \infty} |x_{31}| \leq \sqrt{\frac{\varepsilon_3}{2k_2}}.
\]  
(45)

Then, using inverse transformation (22) and (45) it can be shown that errors in task space become
\[
\|\bar{q}_i\| \leq \sqrt{\left( \frac{\varepsilon_3}{2k_2} + 1 \right) \varepsilon_3 + \frac{1}{2} \varepsilon_1^2 \sqrt{\frac{\varepsilon_3}{2k_2} + \frac{1}{4} \varepsilon_2^2}},
\]  
(46)

where $\bar{q}_i = \begin{bmatrix} \bar{q}_2 & \bar{q}_3 \end{bmatrix}^T$.
C. Control input saturation

The condition of stable motion formulated by (16) determines set of maximum values of velocities for which \( x_{ICR} \in \mathcal{X}_n \). Taking into account this limitation we assume that kinematic control signal \( \eta \) is scaled as

\[
\eta = \begin{cases} 
\eta & \text{if } s \leq 1, \\
\frac{\eta}{s} & \text{if } s > 1,
\end{cases}
\]

(47)

where

\[
s = \frac{|v_y\omega|}{\Gamma}
\]

(48)

For controller considered here the procedure given by (47) is not sufficient and according to Lyapunov analysis it is necessary to scale also frequency signal \( u_\omega \) and time varying gain matrix \( \Psi \). In order to do that we introduce time-scaling method and define scaled time as follows

\[
\tau_s = \int_0^\tau \kappa dt,
\]

(49)

where

\[
\kappa = \begin{cases} 
\frac{1}{s} & \text{for } s \leq 1 \\
1 & \text{for } s > 1
\end{cases}
\]

(50)

Next original variables \( u_\omega \) and \( \Psi \) become

\[
u_{\omega s} = \mu_{\Psi} u_{\omega}
\]

(51)

and

\[
\Psi_s(\tau) = \Psi(\tau_s).
\]

(52)

Now using these new variables in the controller with control \( v_s \) and assuming that \( f = 0 \) (i.e. regulation problem is considered) and \( |d| \) is low enough (since \( v_y \) is linearly dependent on \( \omega \) according to (2) it is reduced in the same way as control signal) is quite easy to achieve the similar stability result as in the case where input saturation is not taken into account (34).

IV. SIMULATION VERIFICATION

In order to show the effectiveness of presented control algorithm in the task of point stabilizations numerical simulation in Matlab/Simulink environment have been conducted. The model of SSMR used here is based on kinematic equation (1) and takes into account the part of the dynamics related to reactive lateral force (8). The control is considered at kinematic level since it is assumed that the input are linear and angular velocity of the robot’s body. The parameters of the model have been chosen to correspond to the parameters of the real small experimental mobile robot MiniTracker 4WD (see [7] and [9]) as follows:

\[
a = b = 0.039 [m], \ m = 1 [kg], \ g = 9.81 [m/s^2].
\]

Additionally it was assumed that friction coefficients for rear and front wheels satisfy: \( \mu_1 = \mu_2 = 1 \) and \( \mu_3 = \mu_4 = 0.8 \), respectively. For numerical reasons function \( \text{sgn} \) has been approximated as follows: \( \text{sgn}(\gamma) \approx \tanh(10\gamma) \).

The parameters of the controller have been selected as

\[
k_1 = k_2 = 5, \ \rho = 10, \ \varepsilon_1 = \varepsilon_2 = \varepsilon_3 = 0.05, \ \psi_{10} = \frac{\pi}{2}, \ \psi_{20} = 2, \ \alpha_1 = \alpha_2 = 2, \ \xi = [0 \ 1]^T.
\]

Without lack of generality we assume that absolute value of linear and angular velocity is not limited (it can be easily included during calculation of scaling function \( \kappa \)). Instead of it only limitation of \( |v_y\omega| \) has been considered.

Numerical simulations have been conducted within the time horizon of \( t_h = 10[s] \) and for the following initial conditions: \( x(0) = 0, \ y(0) = 1, \ \theta(0) = 0 \).

In the first case it is assumed that \( \Gamma = 40 \). This assumption clearly does not satisfy the condition of stable movement given by (16). The results of regulation can be observed from Fig. 3(a)-3(d). According to the path depicted in Fig. 3(a) with stroboscopic view one can conclude that in the beginning of regulation, when velocities are relatively high, orientation of the robot is significantly different to the direction of the vector tangent to the path. It means that nonholonomic constraint is violated significantly. This observation can be confirmed as shows \( \omega \)-coordinate of ICR (see Fig. 3(c)) which goes out from the set \( \mathcal{X}_n \). Hence, magnitude of lateral velocity is quite high with respect to angular velocity (compare Fig. 3(d)) that means excessive skidding. Notice that condition \( 2|v_y| \leq \rho \) during regulation holds – as a result performance of the controller is relatively good and control purpose is achieved. From Fig. 3(b) one can see that errors have been bounded to the assumed neighborhood of the origin.

For the second simulation experiment condition (16) has been satisfied using \( \Gamma = 8 \). The results are presented in Figs. 4(a)-4(d). Considering Fig. 4(a) one can easily observe that robot’s movement is less extensive and the vehicle is almost oriented along the path. In comparison to previous case where limitation of velocities were lower, position and orientation errors (see Fig. 4(b)) converge to the desired neighborhood of the origin slower as the control signals achieve smaller magnitudes (see Fig. 4(d)). Notice that \( x_{ICR} \) depicted in Fig. 4(c) remains in the set \( \mathcal{X}_n \) - hence skidding effect is highly limited (see value of \( |v_y| \)).

V. SUMMARY

In this paper full-state regulation problem with respect to skid-steering mobile robot has been investigated. The proposed controller is based on tuned oscillator (see also [4] and [5]) which provides sinusoidal-like signals with time-varying amplitude, which are tracked by the transformed state vector. In order to limit skidding effect control scaling algorithm has been proposed and next illustrated by simulations. In comparison to previous solutions (see [2], [8]) no virtual nonholonomic constraint has been assumed. Instead, lateral velocity of the robot has been treated as a disturbance which has been considered during control law development.

Future works will be devoted to prove stability of the control system also for trajectory tracking task and to extend formally this approach to dynamic level.
